

BIOKENAF – QLK5-CT2002-01729

6th technical meeting VOLOS, 22-23 November 2005

FOOD
AGRICULTURE
ENVIRONMENT

INRA main involvement

- *WP2: Adaptability and productivity field trials*
 - Task 2.2: Effect of different **sowing dates** and **plant populations** on biomass yields
 - Task 2.3: Effect of **irrigation** and **nitrogen fertilization** on biomass yields
- *WP3: Development of the crop growth simulation model*
 - Task 3.1: Development, calibration and validation of the **crop production simulation model**
- *WP6: Environmental impact assessment and life cycle analysis of kenaf production and use*

WP2: Adaptability and productivity field trials

FOOD
AGRICULTURE
ENVIRONNEMENT

1. Presentation of trial conditions

FOOD
AGRICULTURE
ENVIRONNEMENT

Trial location

Estrées-Mons
INRA centre

- **Climate:** Oceanic temperate
- **Soil type:** Deep loamy soil
(Ortic luvisol, FAO
classification)

Meteorological data in 2005

Temperature and rainfall amount in Estées-Mons

-Rainfall less important in June, more important in July

-Temperature more regular than usual

Experimental design in 2005

25					5.4	5.4	5.4	5.4	5.4	50
2.5	6.5	6.5	6.5	3						
S2	V1D1R1	V1D1R2	V1D1R3							
	V2D1R1	V2D1R2	V2D1R3							
	V1D2R1	V1D2R2	V1D2R3							
	V2D2R1	V2D2R2	V2D2R3							
S1	V1D1R1	V1D1R2	V1D1R3

	V2R1'	V2R2'	V2R3'						

-V1: Tainung 2

-V2: Everglades 41

- 6 repetitions

Field observed the 14 October 2005:

Crop management sequence

Sowing

date 1: 26/04/2005

date 2: 23/05/2005

Sowing machine: pneumatic seed drill

Varieties: Everglade 41 and Tainung 2

Density: 80 plants/m²

Fertilisation

none

Weed control

date: 12/07/2005

type: manual weed control

Irrigation

none

Weed control is a problem:

Mechanical or chemical
solution has to be performed

2. Results

FOOD
AGRICULTURE
ENVIRONNEMENT

2.1. Losses at emergence

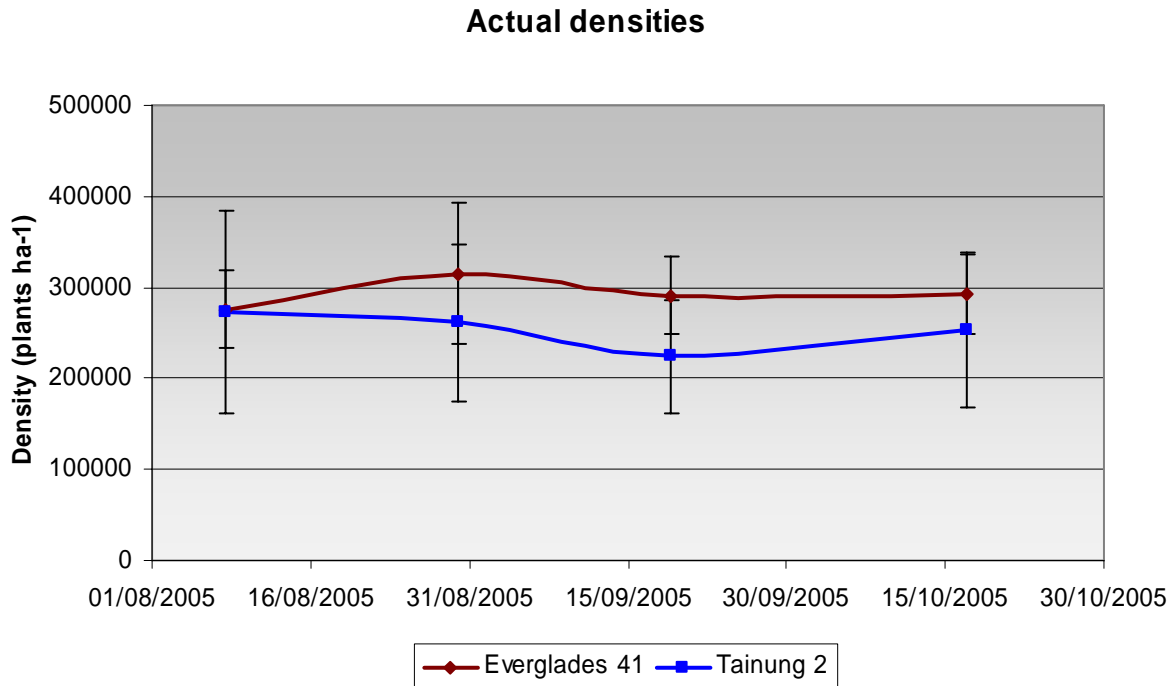

2.2. Biomass yield

2.3. A specific problem in 2005

2.4. Other data

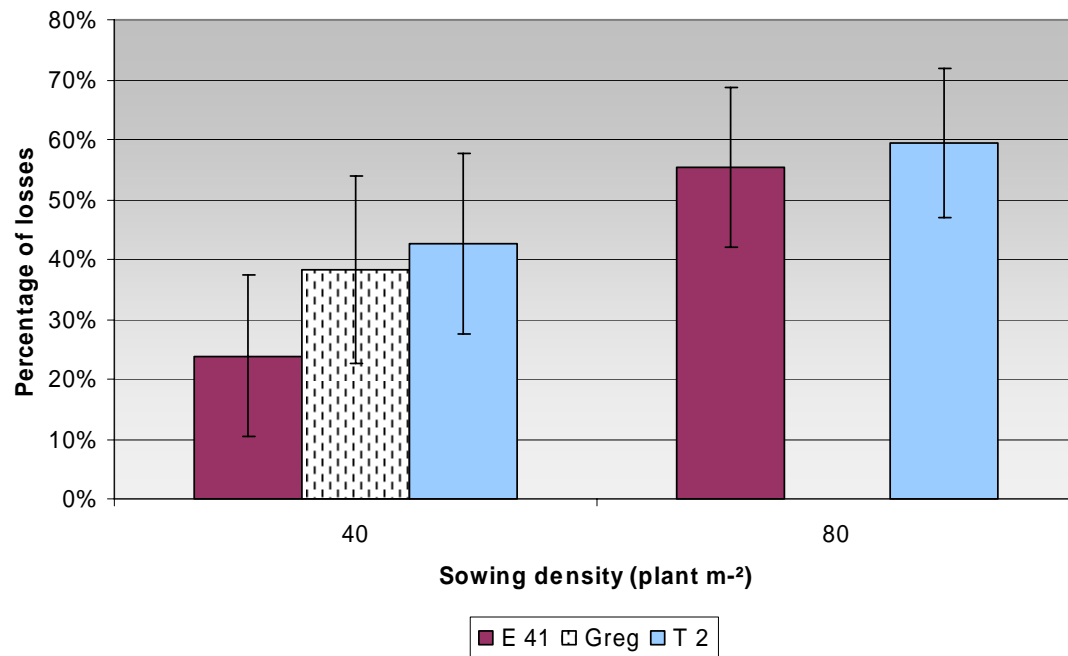

Densities and losses at emergence

- **Very important losses**
- Difference between varieties only in September due to the heterogeneity

Losses at emergence (2003-4-5)

Losses at emergence as a function of sowing density and variety

- More losses for high densities
- No difference between varieties
- T2 more sensible ?

Losses at emergence are a very important problem (2 total losses of trials)

- Seed fungic protection (White et al. 1971)
- Starter fertiliser (?)
- Case of soils favourable to crusts: cropping management adapted
- Other problem?

2.1. Losses at emergence

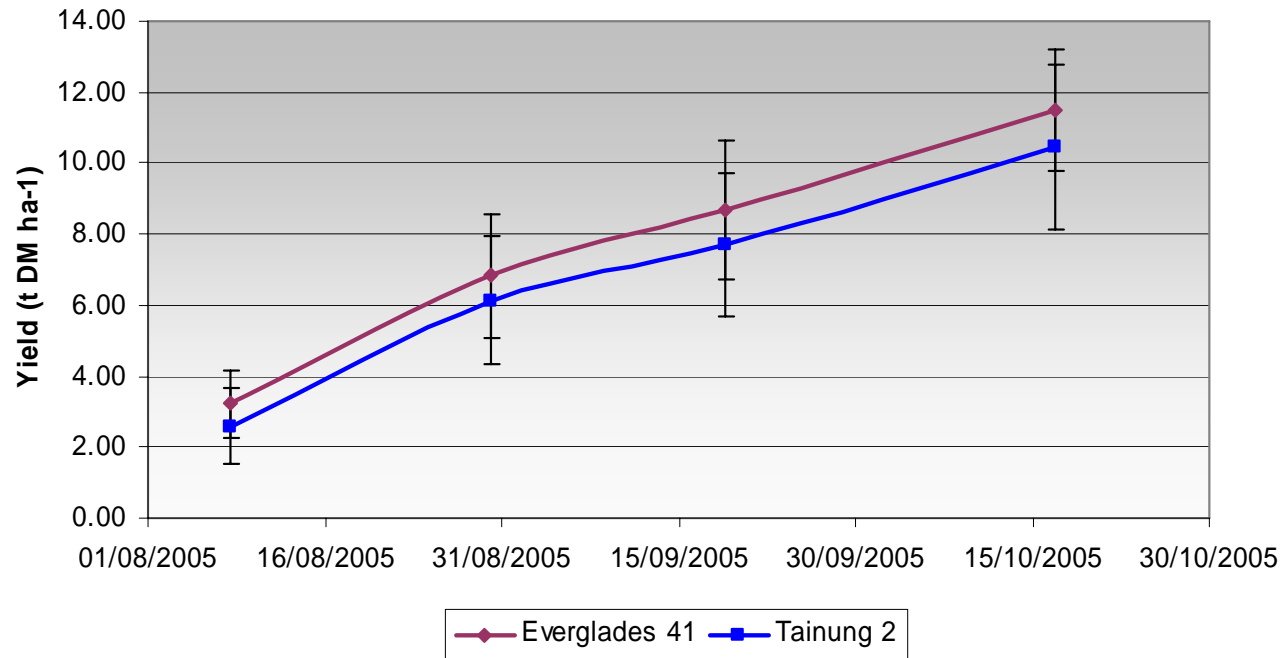

2.2. Biomass yield

2.3. A specific problem in 2005

2.4. Other data

Total dry matter yield depending on variety

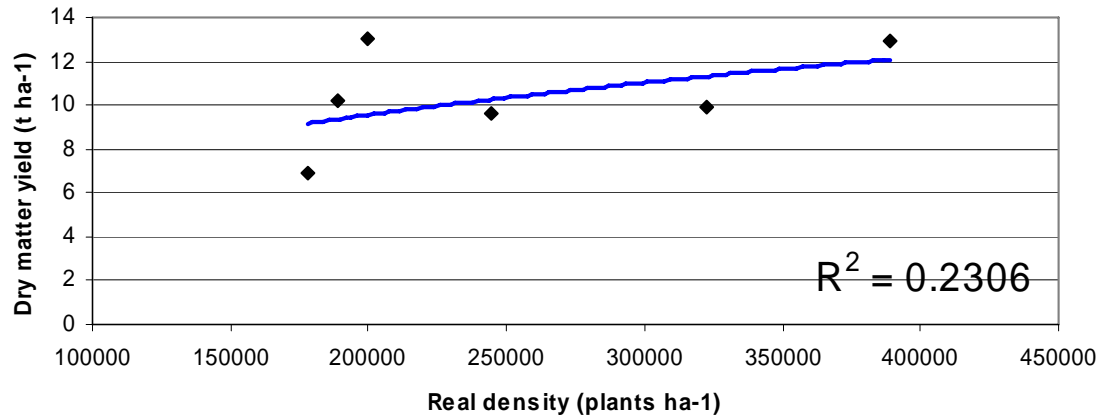

-Tainung 2 DM yield: **10.5 +/- 2.3 t/ha**

-Everglades 41 DM yield: **11.5 +/- 1.7 t/ha**

-**No statistical differences (p=0.3 to 0.5)**

Dry matter yield of **Tainung 2** as a function of real density

-No correlation for T2

-Positive correlation for E41

Dry matter yield of **Everglades 41** as a function of real density

30pl/m²: limiting density is not reached

Biomass yield in 2003-4-5

	trial objectif	yield min-medium-max (t MS/ha)
2003	V*S*D	8.9- 11.0 -12.3
	I*N	6.9- 8.6 -9.6
2004	V*S*D	10.0- 10.5 -11.5
	N	8.3- 9.9 -11.2
2005	V*S*D	6.9- 11.0 -13.1

- Medium DM yields varying from 8.6 to 11 t/ha
- No solutions for strong yield improvement

Other similar plant yields

PLANT	DM YIELD	SOURCE
Maize	+/- 17 t	INRA Mons, France
Hemp	6 to 12 t	ITC, France
Sugar sorghum	Until 25 t	INRA Paris, France

- Advantage of kenaf versus maize if we **take into account environmental assessment**

- 
- **Sustainable yield** in the North of France near **10t** of Dry matter per hectare
 - Other plants, better known in France can reach this yield with more security
 - Advantage for kenaf due to low inputs (positive consequences in the cost and the environment)
 - **One critical point: the establishment of the crop (losses at emergence, crusts...)**

2.1. Losses at emergence

2.2. Biomass yield

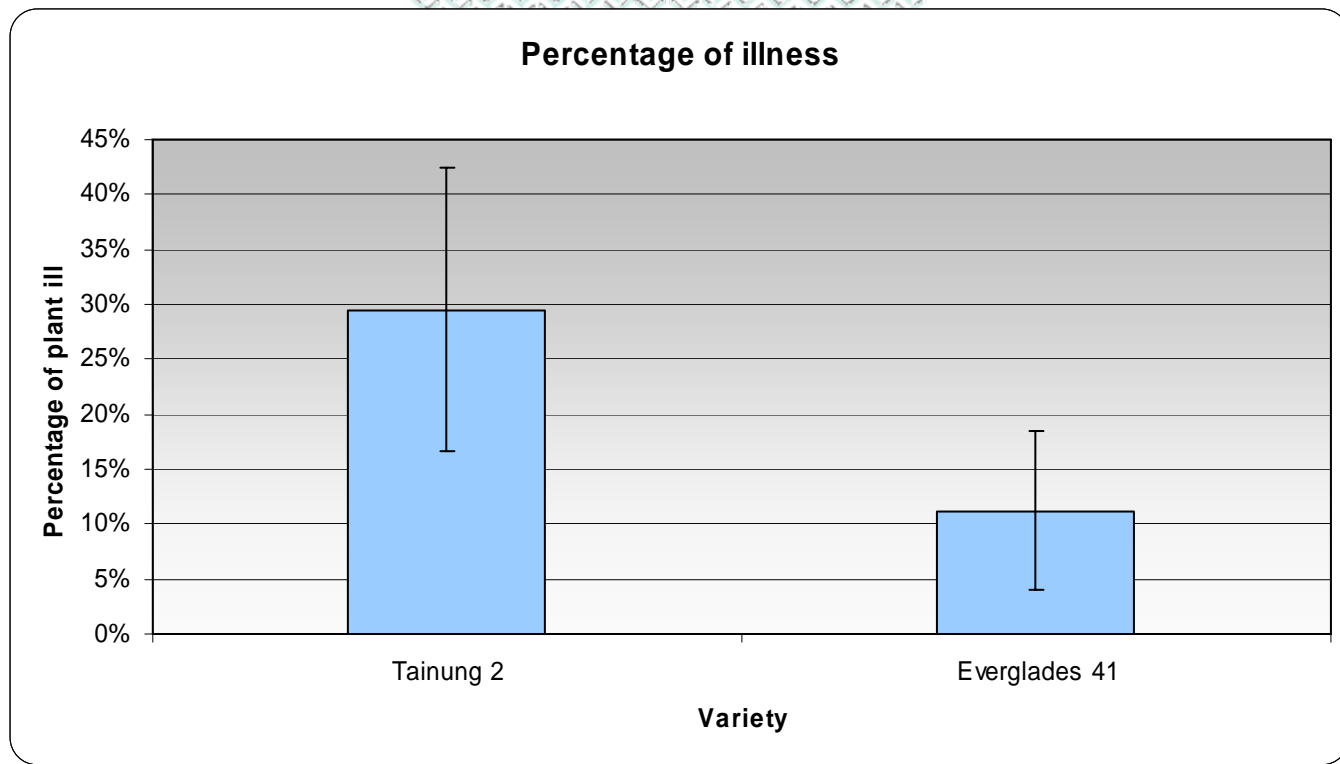

2.3. A specific problem in 2005

2.4. Other data

In September,
attack of an
unspecified disease
was observed
on few plants

- Very important attack and **T2** much **more sensible**
- Suspicion of **Gray mold** (Campbell and O'Brien 1981), exact determination in progress

2.1. Losses at emergence

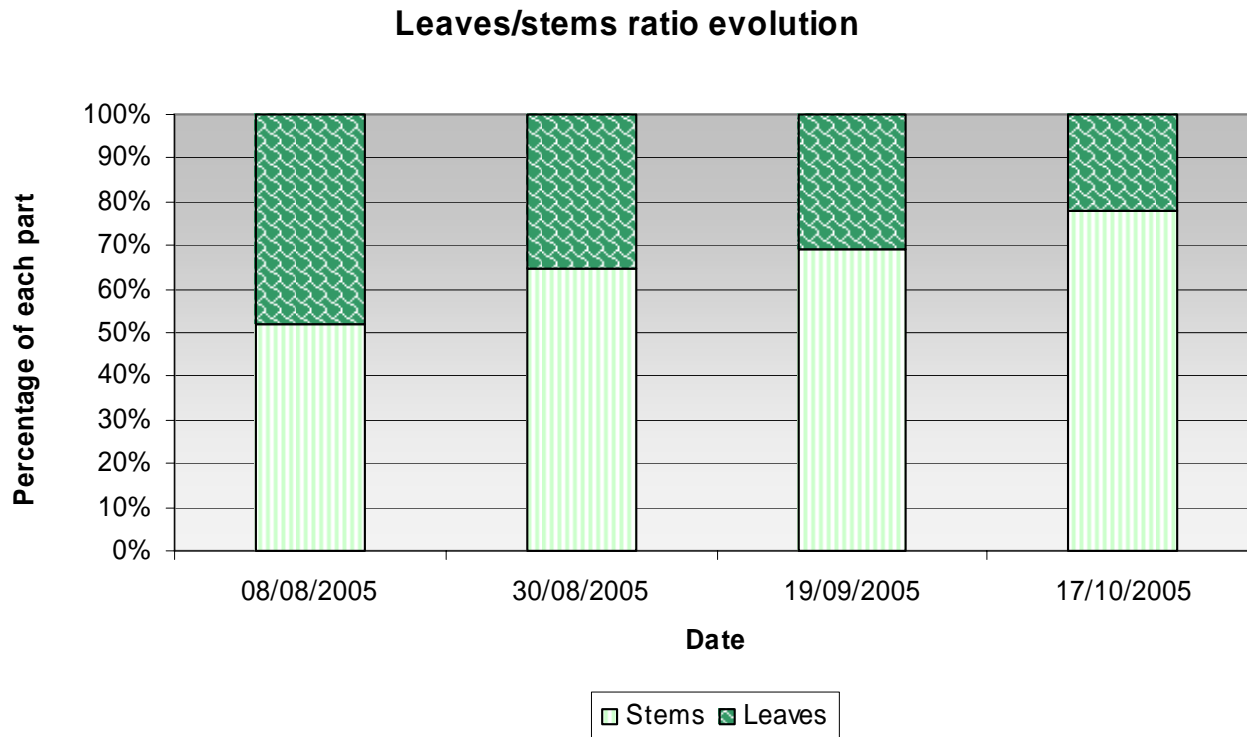

2.2. Biomass yield

2.3. A specific problem in 2005

2.4. Other data

Leaves/stems ratio evolution

-Same trend for E41 and T2

-Total yield mainly explained by stems

Moisture content

Moisture content depending on time

**-Same trend for
E41 and T2**

**-regular
diminution until
75% in October**

Synthesis

FOOD
AGRICULTURE
ENVIRONNEMENT

Irrigation effect

- Positive effect in 2003 and 2004 ... But ...
 - Not for all the samples: interest not so obvious
 - French context: diminution of water use in agriculture → **no irrigation for energy crops**

Fertilisation

- **No differences** observed in 2003 and 2004 on the biomass yield
- Exact needs of the kenaf do not seem to be determined in the literature
- Work in progress: **analysis of the needs** (with soil analysis, plant N content and level of nitrogen supply)

Date of sowing

- No comparison in 2003 and 2005
- In 2004, confusion between sowing date and sowing density: no recommendations ... But...
- One more time, for a sustainable yield, the **most important is to wait very favourable conditions (minimum risk of high rainfalls, high temperatures...)**

Sowing density

- In 2003, **no differences** were observed between densities
- In 2004, confusion between sowing date and sowing density
- In 2005, **30 pl/m², not a limit** but if more caution to the cost (more losses with highest density)

Variety

- Each year, differences between varieties are not significant
- In 2005 **Tainung 2** appeared more variable in all the analysis and much more sensible to the disease observed

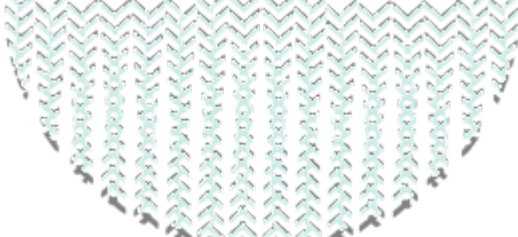

Conclusion

FOOD
AGRICULTURE
ENVIRONNEMENT

- 
- **Few differences** were generally observed between treatments in 2003, 2004 and 2005
 - Very important problem for crop establishment

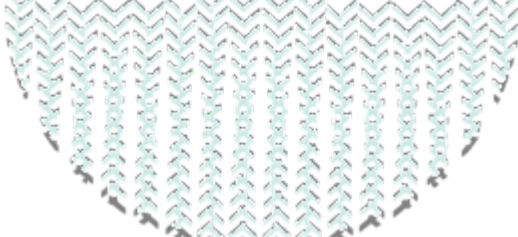

Thus, for a sustainable yield we have to minimize risks of losses at emergence and/or during the growth period instead of maximizing the yield

MODALITY	CONCLUSION
Irrigation	0
N-Fertilisation	Analysis of the needs in progress
Sowing date	waiting for very favourable conditions
Sowing density	Objective of 30-40 plants/m²
Variety	Everglades 41

WP3: Development of the crop growth simulation model

- 
- $DM = x * \Sigma PAR_{intercepted}$
 - $PAR_{intercepted} = PAR_{incident} * \epsilon_i$
 - $PAR_{incident} = 0.5 \text{ Global Radiation}$
 - $\epsilon_i = 0.95 * (1 - \exp(-k * LAI))$
 - $k = 0.56$ [Muchow R.C. 1992]
 - $LAI = y * \Sigma \theta$ (threshold 12°C)
 - x and y determined by linear regressions

2005

Dry matter accumulation as a function of intercepted PAR in
2005 ($k=0.56$)

RUE = 2.017 g.MJ⁻¹ (Muchow RUE = 1.20 g.MJ⁻¹)

Explanations

- Better RUE than Muchow
- In his trial Muchow reach a maximum of 2000 MJ.m⁻² (600 MJ.m⁻² for us)
- Thus **our limitation is the PAR_{intercepted}...**
...and not cultivation techniques
- We could test a **kenaf variety with early maturity** if it is not sensitive to low temperatures
